Aims

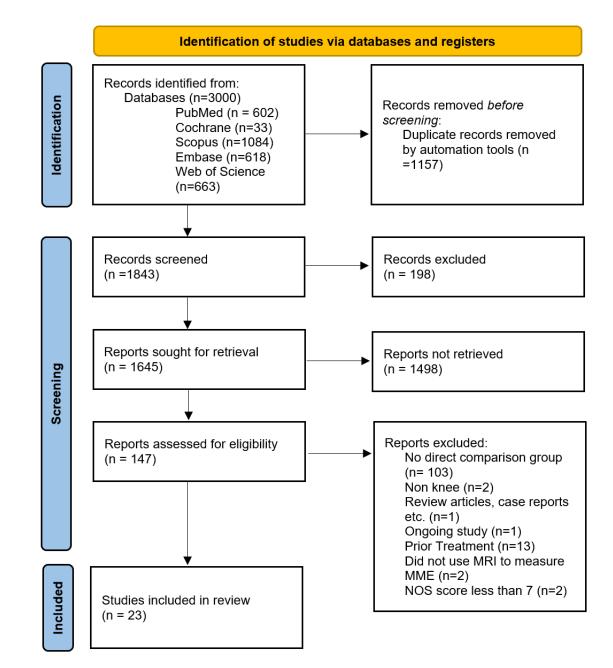

To evaluate if MMRT significantly increases MME compared to non-root tears (NRT) and no tears

To determine the clinical outcomes of increased MME

Methodology

- An electronic search of 5 databases using keywords relating to "Meniscus Tear" and "Extrusion"
- Screened 3000 articles and included 23 studies involving 7984 knees in a randomeffects meta-analysis
- All statistical analysis was performed using the Review Manager version 5.3 (Revman, Cochrane Information Management System) software
- Subgroup and sensitivity analysis performed to evaluate for potential sources of heterogeneity

Results

Subgroup analysis: Medial Meniscus Root Tear vs Non-Root Tear (NRT)

- 1. Absolute Meniscal Extrusion (AME)
 - 5 studies, involving 1089 patients
 - MMRT patients had a mean AME of 4.00±1.82 mm
 - NRT patients had a mean AME of 2.79±1.47
 mm
 - MMRT had a **1.12 mm** significantly greater AME than NRT

2. Incidence of Major MME

- 8 studies, involving 2628 patients
- MMRT were 2.51 times more likely to have major MME compared to those who had NRT

Discussion: Subgroup analysis for patients with MMRT

Unclassified, Non-Sensitive

Discussion: Causes of Increased MME in Non meniscal tears and Non OA knees

- 1. No meniscal tears and non-OA knees had a mean MME of **2.18±1.43mm** and **2.33±1.53mm** respectively.
- 2. This may be related to a variety of possible etiologies:
 - a. Meniscal degeneration → meniscus increases in size due to the formation of microcyst and separation of fibrils, altering the meniscus ability to resist hoop strain⁹
 - b. Varus malalignment
 - i. When structurally intact, the meniscus can offset the influence of the varus alignment
 - ii. In meniscus degeneration or with a root tear, varus malalignment becomes significant, increasing the risk of OA progression¹⁰.
 - c. Obese individuals \rightarrow nearly 5x more likely to have increased MME¹¹
 - d. Past knee injury \rightarrow nearly 4x more likely to have increased MME¹¹

Discussion: Future Directions

- Increased MME in an MMRT can be likened to a "total meniscectomy" ¹²
- Root repair achieves superior clinical outcomes compared to partial meniscectomy.¹³
- However, 33.5% of patients treated by meniscal repair underwent conversion to total knee arthroplasty within 10 years¹⁴
- Pre-operative varus alignment and increased post-operative MME are poor prognostic factors of meniscus repair¹⁵
- Currently, root repairs does not significantly decrease postoperative MME¹⁶ and OA progression¹⁷

Conclusion

- 1. Patients with MMRT have higher MME compared to other types of meniscal tears and those without any meniscal tears.
- 2. Patients with knee OA were more likely to have higher MME compared to Non-OA.
- 3. Given the results, the authors recommend that meniscal extrusion be routinely measured in patients to aid with diagnosing, decision-making and prognostication for patients with MMRTs.
