Background

- Minimising postoperative complications and mortality in COVID-19 patients undergoing trauma and orthopaedic surgeries is a priority
- This study developed a predictive nomogram for 30-day morbidity/mortality in patients who underwent orthopaedic and trauma surgery during the coronavirus pandemic in the United Kingdom (UK) during the first peak wave of COVID-19 (2020).

Methods

- Retrospective multicentre cohort study
- Patients with suspicion of SARS-CoV-2 infection who had undergone orthopaedic or trauma (bony or soft tissue procedure) surgery for any indication during the 2020 pandemic
- Multivariable logistic regression analysis was performed
- A nomogram was developed from the logistic regression model

Results

- 2535 patients included
- Independent predictive variables of 30-day complications - Preoperative COVID-19 status, sex, ASA grade, urgency and indication of surgery, use of tourniquet, grade of the operating surgeon and comorbidities (like diabetes, and cardiovascular, renal, pulmonary and cognitive diseases).

Nomogram

Observed versus predicted probability of complications/mortality in our cohort based on COVID-19 status (Calibration; straight line)

Conclusions

- Orthopaedic and trauma surgeons can use nomograms developed in this study as a practical and effective tool in postoperative complications and mortality risk estimation.
