- No conflicts of interest

The Problem

Meniscal Allograft Transplantation (MAT) replaces damaged meniscus tissue with grafts, aiming to restore knee stability and function.

There are 2 fixation methods currently employed

- 1 Soft tissue (suture-only) fixation
- 2 Bony fixation

It has **not** currently been categorically established which method of fixation provides optimal **clinical and functional outcomes**.

Objective of Study

- Meniscal resection (meniscectomy) has been increasingly associated with dire consequences such as **osteoarthritis**, and so preserving the meniscus is of priority.
- Our objective is to analyse existing literature to determine which **method** of **graft fixation in a MAT** provides the **most optimal outcomes** in patients.
- Determining which graft fixation method provides the most longevity, while looking at a **myriad of outcomes** such as infection risk and graft failure resulting in meniscectomy, we aim to have a more **refined understanding of the two fixation methods.**

Method

This meta analysis was performed using the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) criteria.

Identified articles and their corresponding references were reviewed and considered for inclusion according to the selection criteria.

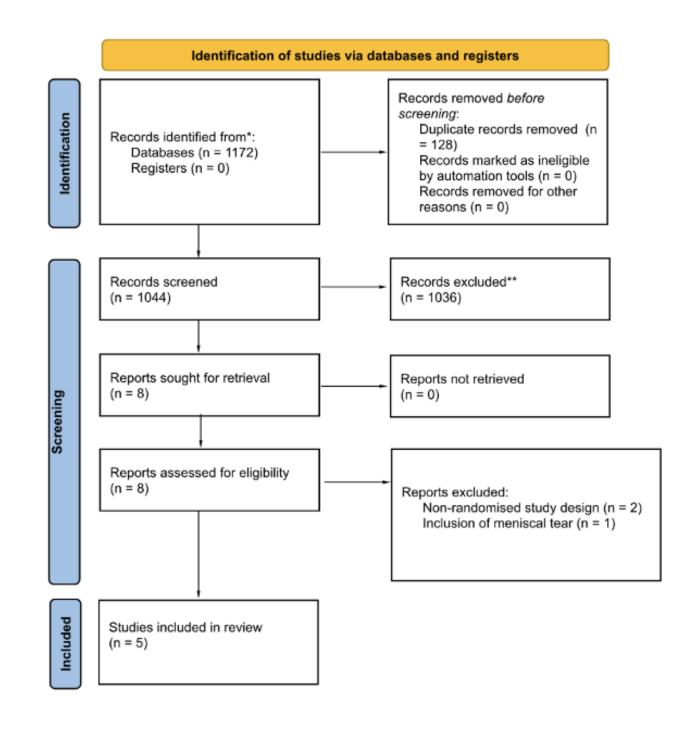

Figure 1. PRISMA selection process Flowchart

Complications and Clinical Outcomes Compared

Complications:

- Infection rates
- Graft failure resulting in meniscectomy
- Graft tears
- Minor graft extrusion < 3mm
- Major graft extrusion > 3mm

Clinical Outcomes:

- Lysholm score
- Tegner Score
- International Knee Documentation Committee (IKDC) score
- Knee Injury and Osteoarthritis Score (KOOS) symptom score

Results

Discussion and Conclusion

- No statistically significant differences in functional and clinical outcomes were noted between bony-fixation and suture-fixation following meniscus allograft transplantation.
- Bony-fixation is generally more widely favoured due to the shorter recovery and healing time as compared to suture-fixation. Our results have shown no statistically significant difference, and hence have disproved this perception.

Strengths

- Strict inclusion of case-control studies to analyse the most optimal method of fixation
- Analysis of **important outcome variables**, such as graft extrusion, graft failure and graft tears.
- Able to establish **no statistically significant** data supporting the widely accepted notion that bony-fixation provides **better outcomes** and suture-only fixation is **less dependable**.

Limitations

- The short to medium term follow-up period is a major limitation to this study.
- Longer follow-up studies are required to assess longevity of meniscal graft, and the inherent risk of osteoarthritis progression.
- This analysis also did not account for differences in clinical outcomes arising from variances in surgical techniques
