

Dynamic Anterior Stabilization for Anterior Shoulder

Instability: A Meta-Analysis and Systematic Review

of Clinical and Biomechanical Studies

Ashraf T. Hantouly, Abdulaziz F Ahmed, Loay Salman, Sathish Muthu, Matthew J Smith, Keith Kenter, Bashir Zikria, Khalid AlkhelaifI, Gazi Huri

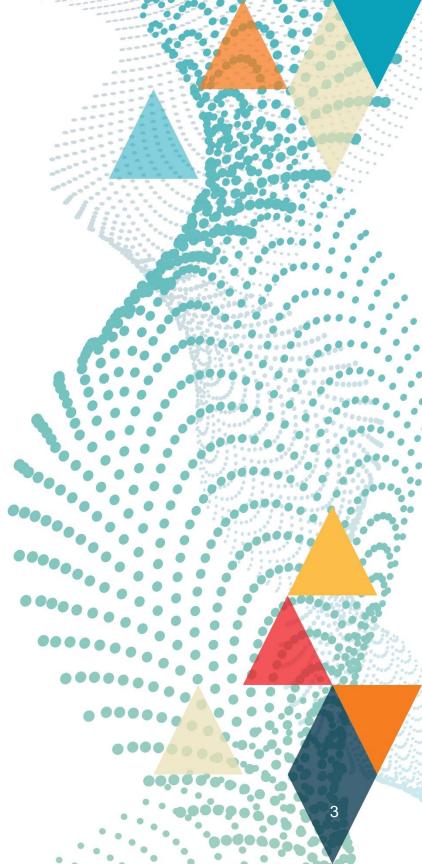

Faculty Disclosure Information

- No potential conflict of interest in relation to this presentation
- I will not be discussing any off-label or unapproved of drugs or products

Background

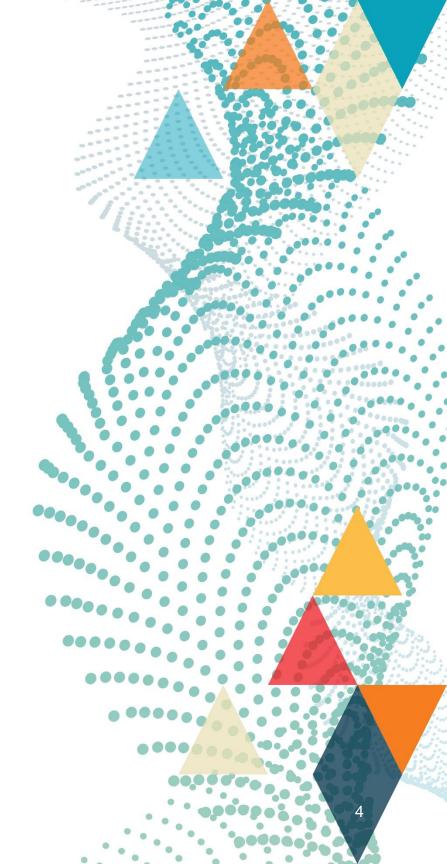

- Anterior shoulder instability (ASI) is common, affecting 23.1/100,000 individuals 1-4
- High-risk individuals, such as younger age at the time of first dislocation, males, and those with hyperlaxity have higher risk of recurrence if treated non-operatively^{5,6}
- Several adjuvant procedures, such as Remplisage and Laterjet, have been introduced to decrease the recurrence rate. However, these procedures are not without complications 6-8
- Dynamic anterior stabilization (DAS) provides an anterior sling augment effect to complement Bankart repair (BR), while minimizing the risk of complications 9,10
- DAS involves anchoring the intra-articular portion of the long head of the biceps tendon or the conjoined tendon to the anterior glenoid rim, combined with Bankart repair
- The biomechanical and clinical evidence supporting DAS remains limited

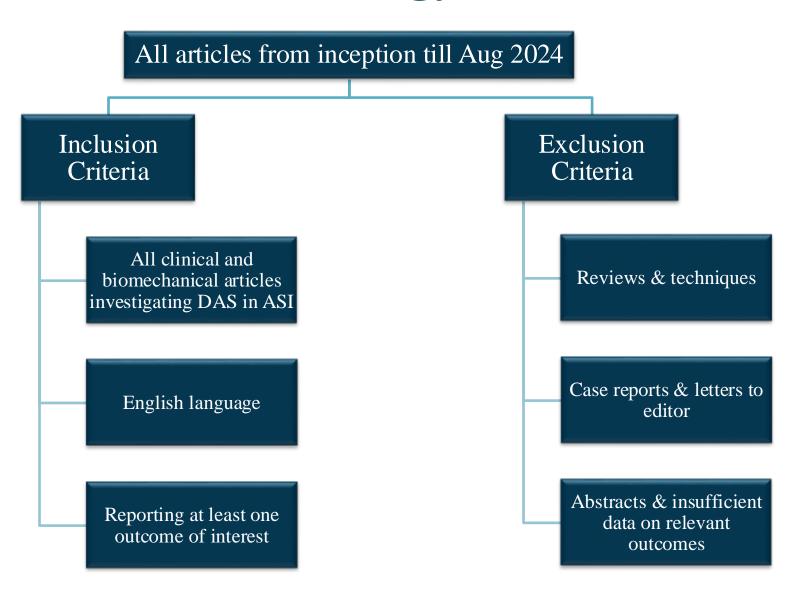

Methods – Aims & Search Strategy

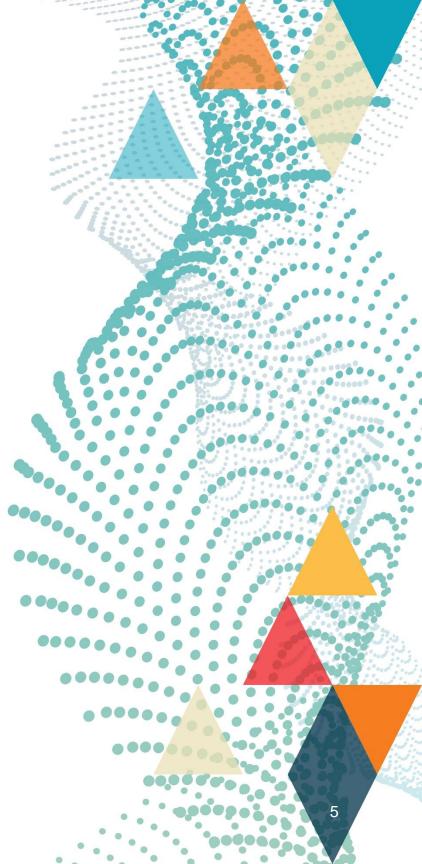

- Aim: To systematically evaluate the biomechanical outcomes, clinical outcomes, and complication rates of DAS combined with BR for ASI
- PubMed, Embase, and Scopus databases were searched from inception until August 2024
- Search terms: [Shoulder] AND [Instability] AND [Dynamic] AND [Anterior] AND [Stabilization or Stabilisation]

Methods

ISAKOS

PRISMA

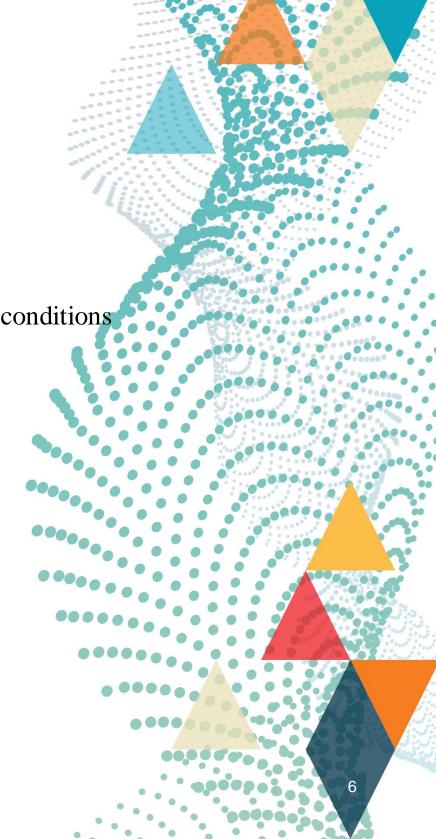

Data of Interest

- **Biomechanical outcomes of interest:**
 - glenohumeral anterior translation
 - Joint stability under various loading conditions
 - Load-to-dislocation

- Clinical outcomes of interest:
 - Patient-reported shoulder scores
 - Range of motion
 - Complication rates

Methods - Analysis

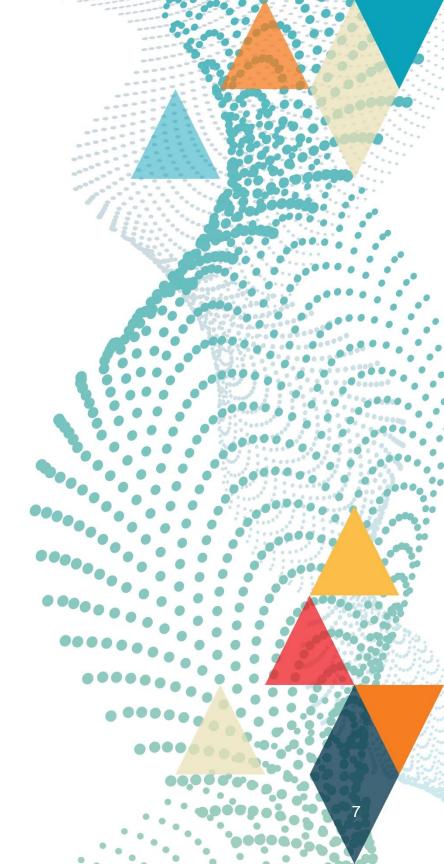

• For biomechanical studies:

- No formal statistical pooling was performed due to heterogeneity in methodologies, including variability in GBL models, treatments compared, and biomechanical parameters assessed
- Descriptive statistics were used.

• For clinical studies:

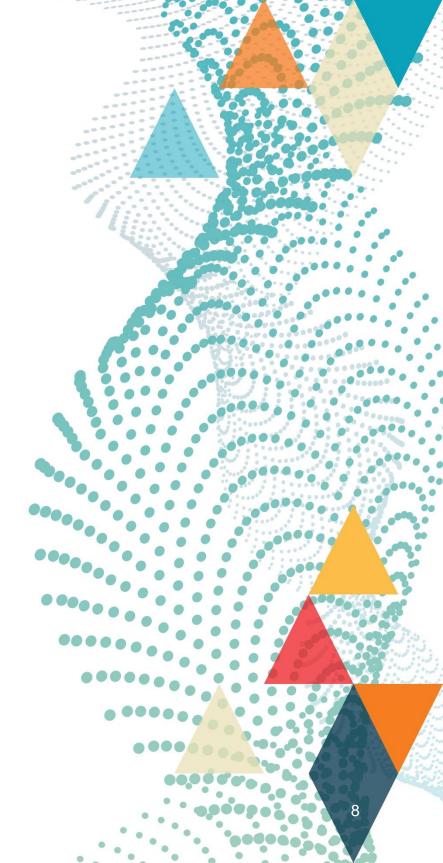

- Pre- to post-treatment weighted mean differences (WMDs) with 95% confidence intervals (CIs) were calculated for continuous outcomes
- Statistical significance was set at a p-value of < 0.05
- Heterogeneity was assessed using the I² statistic
- Random-effects model was applied to account for variations across studies
- Return-to-sport rates and recurrent instability rates were summarized as proportions

Results – Biomechanical Studies

- 60 cadaveric shoulder specimens with a glenoid bone loss (GBL) ranging between 10%-20% were included
- DAS demonstrated significant improvements in anterior glenohumeral stability and load-to-dislocation compared to isolated BR, particularly in models with < 20% GBL and on-track HS lesion
- DAS was less effective than the Latarjet and Remplissage procedures in scenarios involving GBL of 20% or off-track HSL, respectively

Results – Clinical Studies

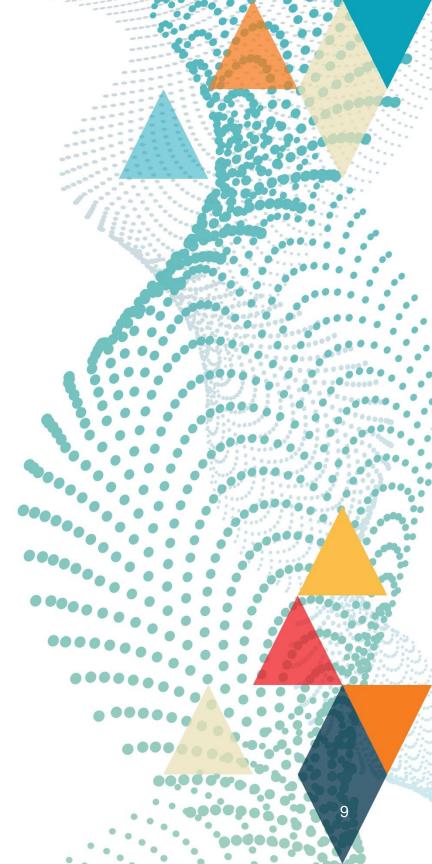

- Three clinical studies | 100 shoulders | Age 23.4 to 31 years | Follow up 24 to 45.3 months | Mean GBL ranging between 8.2% to 10.5%
- All studies reported significant pre-to-post intervention improvements in Rowe scores, with a mean difference of 58.7 points (WMD = 58.7; 95% CI, 50.3-67.2; p < 0.001)

	Post-treatment			Pre-treatment						Mean	diff.	Weight

Test of $\theta = 0$: $z = 2.39$), p =	0.02											
						_	0	20	40				

Random-effects REML model

C Wu 2023: had two arms (DAS using the biceps & DAS using the CJT)

Results – Clinical Studies

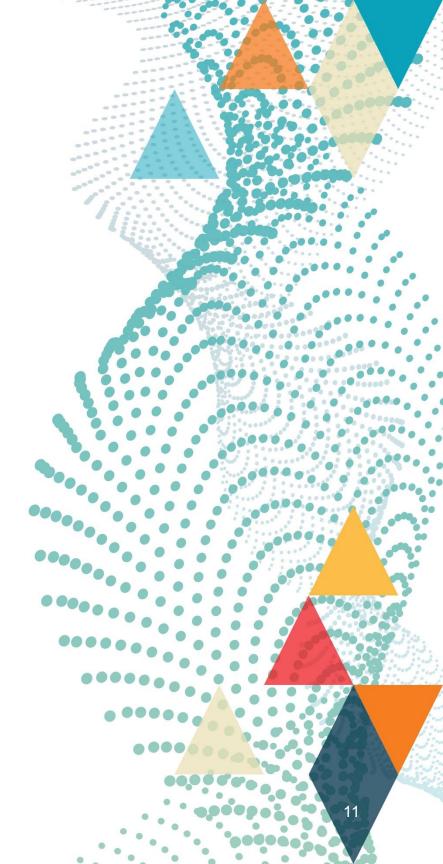

• Return-to-sport:

- 90% for return to sports at any level at two years,
- 71% for returning at a similar level.
- Recurrent instability was reported in 8% (N=8) in the form of:
 - 3 postoperative apprehension
 - 1 subluxation
 - 4 re-dislocations (of which three were found to have an off-track HS)

• Reoperations:

- 2 Revisions to Latarjet in due to recurrent instability (2%)
- 1 capsular release due to post-operative stiffness (1%)

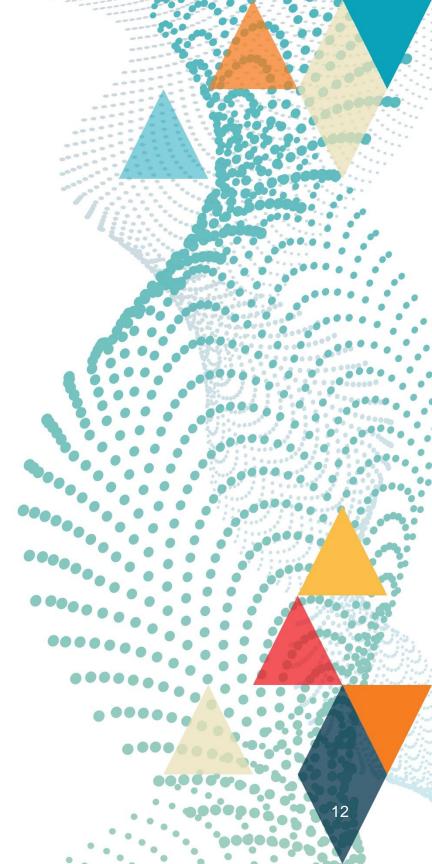

Conclusions

- DAS significantly improves PROMs and RTS
- DAS has a low complication rate in GBL ranging between 8.2% to 18.5%
- The current evidence is limited to Level IV studies and lacks direct comparisons to other established stabilization procedures
- Comparative biomechanical studies support its efficacy in reducing glenohumeral translation and increasing load-to-dislocation when compared to BR alone in models with GBL up to 20%
- Biomechanical studies demonstrated that DAS failed to improve glenohumeral biomechanics when GBL excessed 20%
